## COPYRIGHT NOTICE:

By using the ECSS Training material, developed by ESA, you agree to the following conditions:

1. The training shall take place at your premises and shall be addressed to your staff (internal participants);
2. In case of a training to be given to external participants, the prior ESA written authorisation shall be requested;
3. The ESA Copyright shall always be mentioned on all Training Material used for the purpose of the training and participants shall acknowledge the ESA ownership on such a Copyright;
4. The Training material shall not be used to generate any revenues (i.e. the training and Training Material shall be "free of charge" excl. any expenses for the training organisation);
5. Only non-editable PDF files of the Training Material can be distributed to the participants (nor power point presentations);
6. Any deficiency identified in the Training Material shall be reported to the ECSS secretariat;
7. If the Training Material is modified or translated, the ESA Copyright on such edited Training Material shall be clearly mentioned. A copy of the edited Training Material shall be delivered to ESA for information.
8. You shall always hold harmless, indemnify and keep ESA indemnified against any and all costs, damages and expenses incurred by ESA or for which ESA may become liable, with respect to any claim by third parties related to the use of the Training Material.

# The ECSS E60 branch

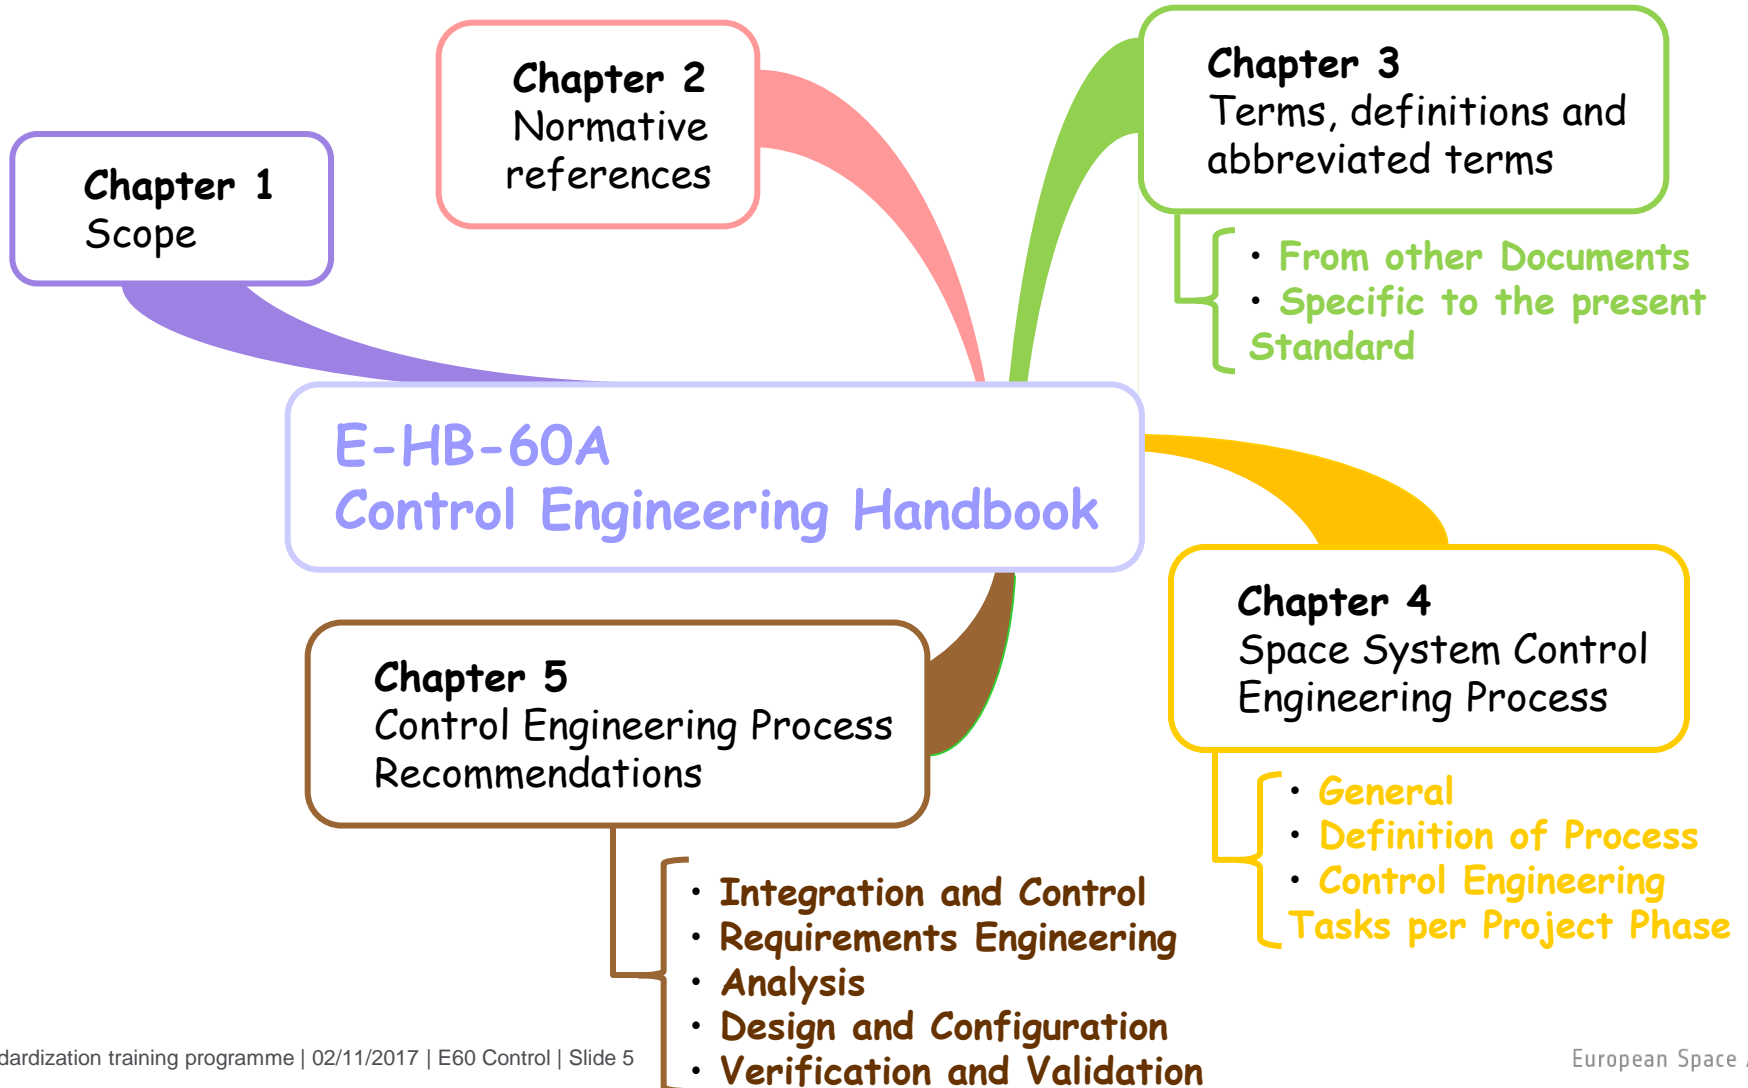

Standardization  
training program  
E60 discipline:  
Control

- This handbook has been adapted from the first document elaborated by the very first Working Group of the E60 branch
  - The initial document was originally published as the Control Engineering Standard ECSS-E-60A in September 2004
  - ECSS Task Force 2 did **not recognize it as a standard** since it was addressing the control engineering process rather than requirements and decided to replace it with a handbook
- This Control Engineering Handbook was published in Dec 2010
  - This **high level** document is quite **generic** since it addresses all systems involving any kind of control (including e.g. thermal control, but not “ground control”)
  - It focuses on the specific issues involved in control engineering and is intended to be used as a structured set of systematic engineering provisions
  - Specialised requirements for attitude control and associated equipment will be found in lower level documents such as the Satellite AOCS Requirements Standard or Star Tracker Standard

# Table of contents

Standardization  
training program  
E60 discipline:  
Control

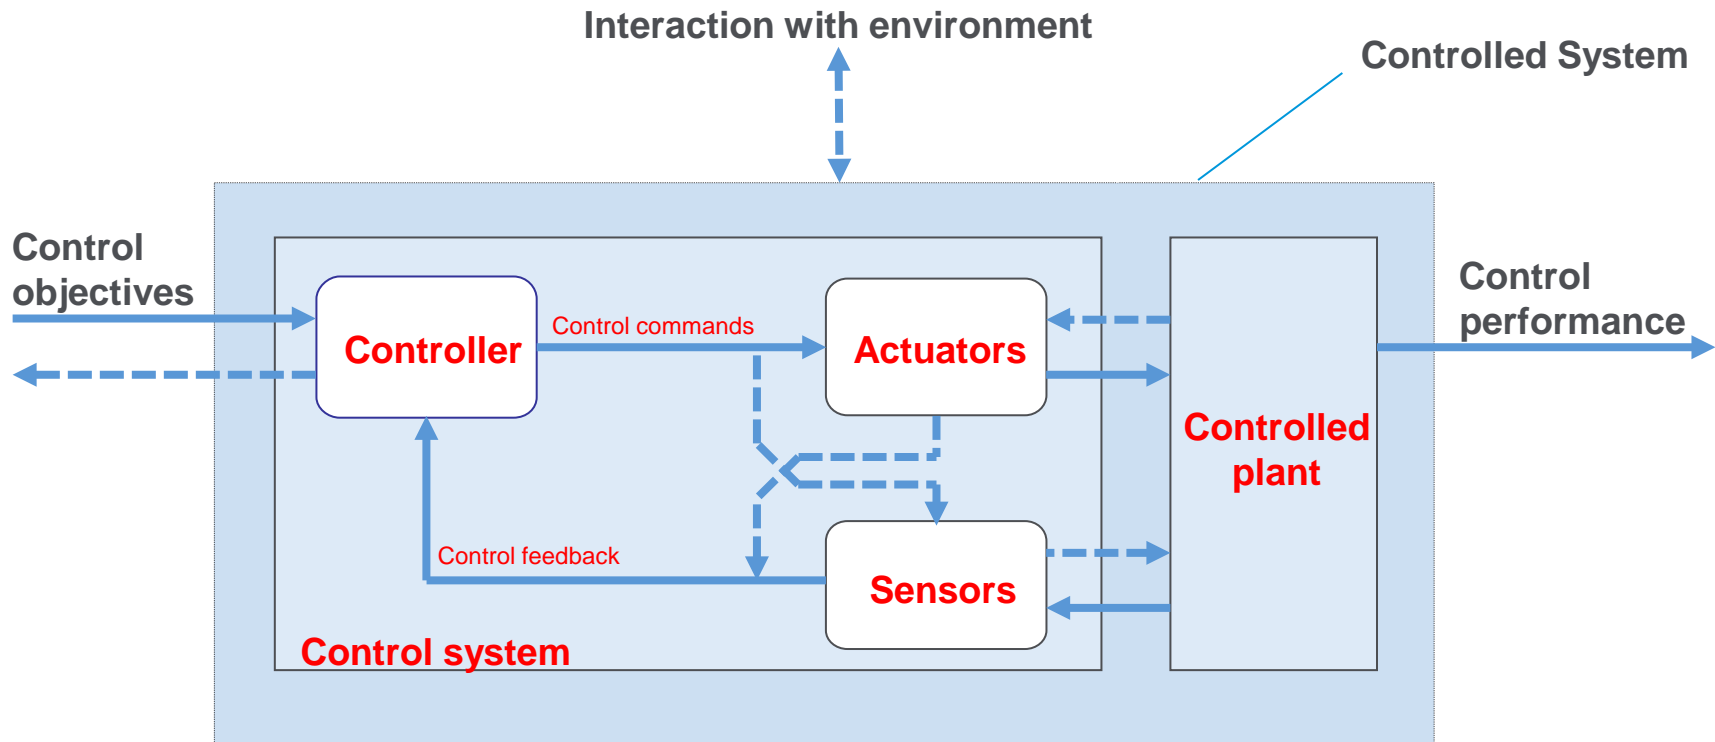

- **Chapter 2** contains the normative references
  - High level ECSS documents: Glossary of Terms, Space Engineering Requirements and Process, Space Project Management
- **Chapter 3** provides definitions of control-related terms
  - e.g. actuator, autonomy, control, controllability, estimated state, estimator, guidance, robustness, sensor, simulation model, stability, state, etc.
- **Chapter 4** describes the space system control **engineering process**
  - main engineering activities defined and characterized by the following:
  - inputs, tasks to be performed, outputs (including documents), milestones and relationship to the project phases
- **Chapter 5** contains **recommendations** for the engineering activities
  - a checklist of recommendations for tasks to be performed and the associated expected outputs

# Introduction

## General Control Structure

Standardization training program  
E60 discipline:  
Control

-  Primary flow of information of the feedback loop
-  Secondary flow of information or physical reaction

## 4.1.2 Control Engineering Activities

- From the general control structure introduced previously, control engineering includes, as a minimum:
  - analysis of the **mission objectives** in order to define the control objectives;
  - **requirements analysis** and specification
  - analysis **and modelling of the controlled plant** and its interaction with the environment;
  - analysis, modelling and specification of **sensors and actuators** (configuration and characteristics) w.r.t. the control requirements;
  - **design** and configuration of the controller;
  - **verification** of the control performance;
  - control system related **ground operations**.
- Consequently control engineering
  - is **multidisciplinary**
    - cannot be performed without significant insight into at least mechanics, dynamics, the space environment and its effects, digital and analogue electronics, control theory, computer systems and networks, software engineering, and operations;
  - has a strong **system aspect**
    - significant level of interaction with the system engineering process specified in ECSS-E-ST-10.

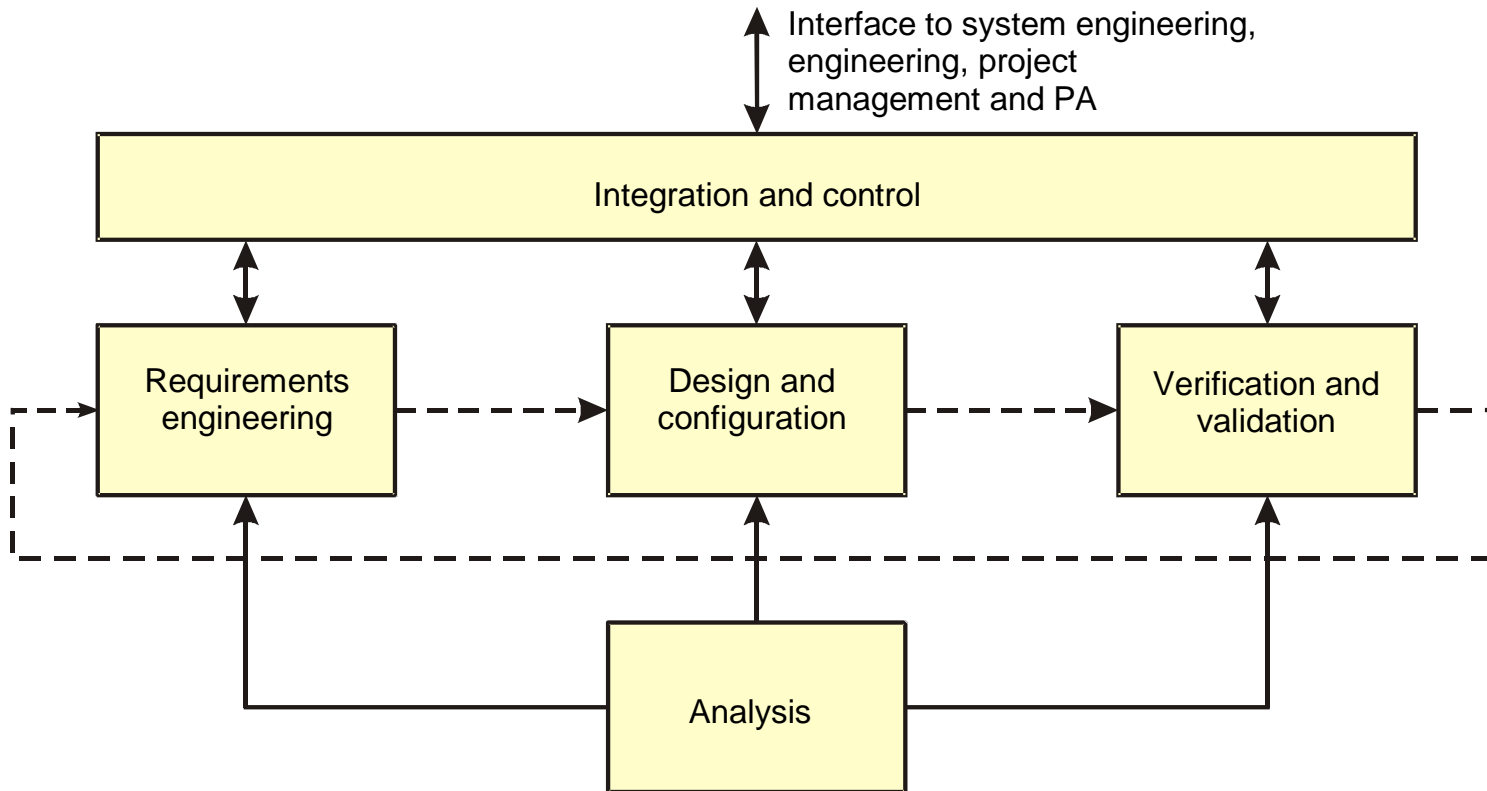

# 4.2 Definition of the Control Engineering Process

- As part of the system engineering process defined in ECSS-E-ST-10, it can similarly be decomposed into the same engineering activities:
  - **Integration and Control**
    - integration of the various control related disciplines throughout all project phases towards the total definition and realization of the controlled system (management, planning, database, interface control, risk control, change and non conformance control,...)
  - **Requirements Engineering**
    - proper interpretation of the mission and system requirements, coherent and appropriate derivation of control requirements, definition of lower component or equipment level requirements and continuous supervision of their status and traceability
  - **Design and Configuration**
    - derivation of a physical control architecture and the controller design capable of meeting the control requirements (supported by proper analyses and trade-offs)
    - derivation of all the control budgets with appropriate budget methodology and margin policy
  - **Analysis**
    - performed at all levels and in all domains for the purpose of resolving control related functional and performance requirements, evaluating control design alternatives, consolidating and verifying control performances and complementing tests
  - **Verification and Validation**
    - demonstrates, through a dedicated process, that the controlled system meets its control objectives and requirements

## 4.2 Interaction between Control Engineering activities

- At various phases of the system development, the control engineering activities are conducted in parallel to support one another in the proper development of the control system and of its components.

- Iterative between system engineering and lower assembly or equipment level engineering
- Progressive from preliminary design to verification and inflight validation.

# 5.1 Control Engineering Process Recommendations

## Integration and Control

### → INTEGRATION AND CONTROL

- Contribution to system engineering data base and documentation
  - Control engineering provides inputs to the system engineering database concerning controller data, and control related sensor and actuator parameters (e.g. flight dynamics database).
  - Control engineering provides a consistent set of control related documentation for the complete development process which is in line with the general system documentation.
- **Budget and margin philosophy for control**
  - **For control related budgets with several contributors, summation rules are defined and used consistently throughout the design process. A margin policy is established and applied. Budget methodology and margin philosophy can evolve during the development according to the level of maturity of the control system.**
- Support to change management involving control
  - Control engineering:
  - supports the management of nonconformances related to control.
  - handles changes related to controller design and implementation.
  - reviews changes in control related disciplines.

# 5.2 Control Engineering Process Recommendations

## Requirements Engineering

### → GENERATION OF CONTROL REQUIREMENTS

- **Control requirements**
  - derived from the directly applicable system requirements
    - taking into account constraints imposed by other system requirements
    - e.g. electrical power, mechanical configuration, thermal conditions and operations
  - **allocated to lower level requirements for the control components**
    - controller, sensors and actuators
    - iterative allocation process, supported by analyses and tests
- **Control requirements engineering**
  - maintains traceability and justification of the control requirements
    - in line with the system requirements engineering process
  - considers system FDIR requirements and failure management definitions
  - supports system requirements engineering
    - to identify and eventually resolve conflicts between requirements, requirements ambiguities and conflicts between requirements and environmental factors or design constraints
- **Control engineering**
  - defines and justifies any control requirement generating a specific system constraint
    - through an appropriate document (e.g. DJF)
    - e.g. minimum allowable thruster tilt for plume effect limitation, sensors/actuators implementation w.r.t. FOV, alignment, mechanical stiffness, eigen-frequencies

# 5.3 Control Engineering Process Recommendations

## Analysis Methods and Tools

Control engineering activity	Analysis tasks	Usual methods and tools
Requirements engineering	<ul style="list-style-type: none"> <li>- requirement analysis</li> <li>- requirements feasibility assessment</li> <li>- disturbance quantification</li> <li>- error source identification and relevant numerical figures allocation to budgets</li> </ul>	<ul style="list-style-type: none"> <li>- analytical relationships and models</li> <li>- spreadsheet analysis tools</li> <li>- control CAE tools</li> <li>- control, environment, sensors, actuators and plant models</li> </ul>
Design	<ul style="list-style-type: none"> <li>- numerical trade studies in support of control architecture definition</li> <li>- numerical analysis to support control design</li> <li>- disturbance effects detailed analysis</li> <li>- stability</li> <li>- robustness</li> <li>- sensitivity to additional or parametric disturbances</li> <li>- performance against applicable requirements</li> <li>- control budget numerical figures consolidation</li> </ul>	<ul style="list-style-type: none"> <li>- analytical relationships and models</li> <li>- spreadsheet analysis tools</li> <li>- 3D CAD system model</li> <li>- control CAE tools</li> <li>- closed-loop simulation (including detailed control, environment, sensors, actuators and plant models)</li> <li>- simulation data analysis tools (e.g. statistical methods)</li> <li>- time-frequency domain methods</li> <li>- linear and non-linear methods</li> </ul>
Verification	<ul style="list-style-type: none"> <li>- performance analysis</li> <li>- test data analysis resulting from H/W-, S/W- and human-in-the-loop tests</li> <li>- inflight data analysis</li> <li>- support to payload data evaluation</li> </ul>	<ul style="list-style-type: none"> <li>- closed-loop simulation (including detailed control, environment, sensors, actuators and plant models)</li> <li>- test data evaluation tools (e.g. statistical methods)</li> <li>- telemetry data processing tools</li> <li>- control CAE tools</li> </ul>

# 5.4 Control Engineering Process Recommendations

## Design and Configuration

### → OPERATIONAL DESIGN

- The logical organization of the functions leads to a logical or operational architecture made up of a set of control modes and transitions between these modes
- Control engineering defines the operational control architecture, which consists of a set of control modes and transitions between modes covering all specified (nominal and non-nominal) conditions of operations of the control system
- The composition of functions and allocations to a control mode is based on existing and common knowledge (experience) of optimum use of sensors, actuators, controllers and operational items
- The operational control architecture is usually presented in the form of diagrams showing control modes, transitions and data flows

# 5.5 Control Engineering Process Recommendations

## Verification and Validation

### → FUNCTIONAL AND PERFORMANCE VERIFICATION

- **Verification by analysis**

- The **performance** of the controlled system is demonstrated by closed loop analysis based on the use of system representative **simulation models**. The verification covers all configurations of control modes, sensors and actuators, including backup configurations
  - **Worst cases conditions** are generally used w.r.t system dynamical and geometrical configurations, including FDIR aspects and the associated possibly degraded configurations
- When relevant or possible, verification by analysis is **supported by H/W testing**
  - A typical example is to correlate a sensor mathematical model, including its parameters, with H/W tests results

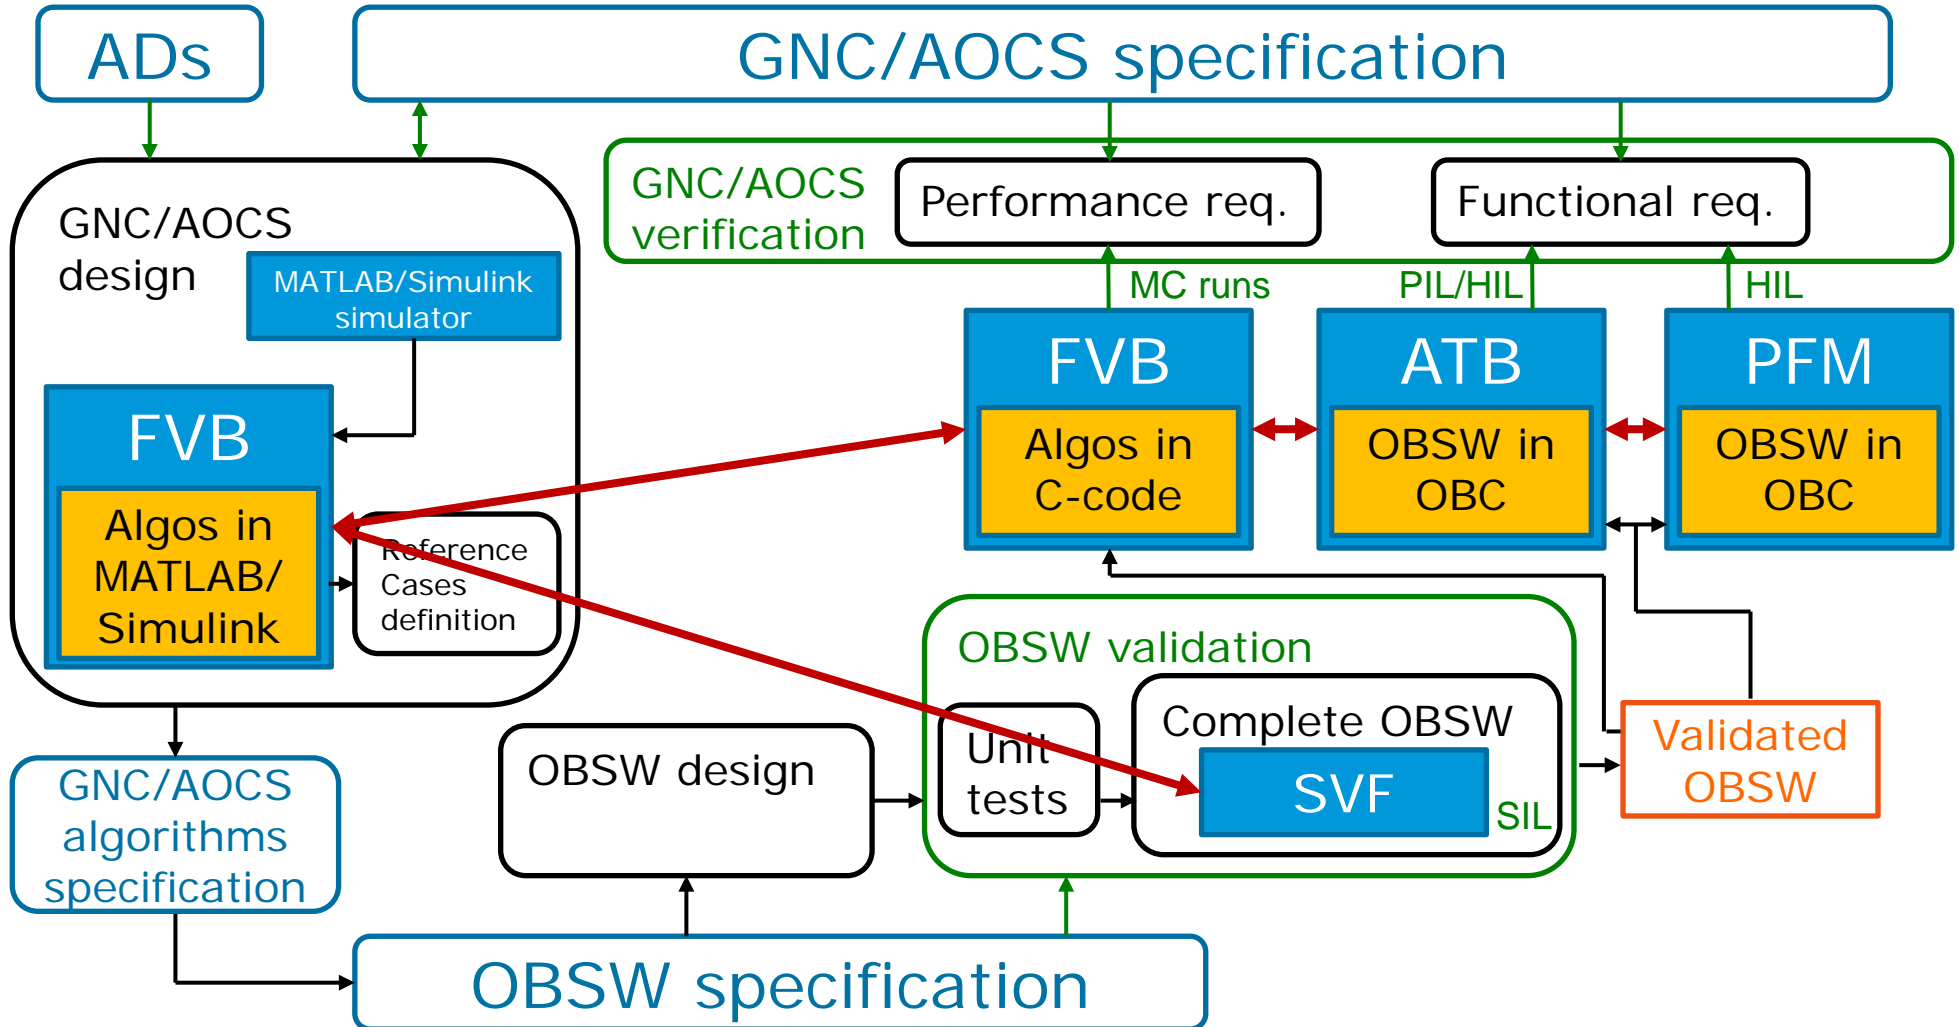

- **Verification with flight H/W and S/W**

- The control verification process includes, when relevant, **functional validation in closed-loop tests** with flight S/W and flight H/W models or flight representative models.
  - The real sensors are stimulated by the EGSE
  - The stimuli can be electrical (test connector) or physical (detector level)

# BACK UP SLIDES

# Summary of GNC/AOCS Functional Chain Verification Logic

Standardization training program  
E60 discipline:  
Control

- Due to the tight interconnection between GNC and AOCS subsystems and OBSW, a joint verification process is needed (at avionics level)
- Avionics verification includes:
  - GNC/AOCS **Performance Verification campaign**, to validate the GNC/AOCS requirements, to check the tuning the GNC/AOCS parameters, and verify closed-loop performance on the FVB
  - **OBSW Verification campaign**, which entails SW module-level testing, HW/SW models verification and calibration, and finally OBSW integration and final verification on the SVF
  - **Functional Chain Verification** campaign, which includes **real HW** and has system-level oriented objectives. It is performed on the SVF, on the ATB, and on PFM
  - **AIT campaign**, which includes verification of system interfaces and is performed on PFM

# AOCS interfaces

Standardization  
training program  
E60 discipline:  
Control

## System / Mission

- Mission reqt (pointing, agility, availability, coverage, ...)
- Microvibration or optical constraints ...
- Mode design, estimation and control tuning, FDIR, ...

## SW and HW

- CPU and delay budget
- Format, bus ...

- Control tuning
- Algorithm complexity limit

## Mission analysis

- Launcher separation conditions
- Orbit
- Acquisition mode tuning
- Perturbation level
- Maintenance mode design

## Communications and data

- Antenna pointing reqt

- control, safe mode design, data to down/uplink

## Thermal

- PF and PL Thermal const.

- Modes design, control tuning, FDIR, safe mode design

## AOCS design

## Ground operations

- Post-processing reqt
- Availability

- Autonomy level, control and estimation design

## Structures and configuration

- mass, inertia, surfaces
- blinding, multipath, ...
- perturbation level
- sensor/actuation errors

## Power

- SA pointing

- Control design, safe mode design

And also cost, propulsion...
